

Object Oriented Programming - Exercise 4

These exercises are a complement to lecture 4

Solutions to this exercises should be shown on-line to the teaching assistant (either during the current pass or at the beginning of the next pass). These solutions are part of the examination of the course!

Use the applet framework and implement an applet that can display a bar chart. The applet should obtain the chart values from a set of *param* tags, from a html file. The bar chart should represent the same information as in exercise 3 (total income for a month and the 3 outcomes: rent and food, books, closed and entertainment).

Connect this exercise to the solution in exercise 3. Means that the html file will be automatic updated when changing in the Mode (StudentGadget class). So the html file will be another observer view.
