

# Integrating an 802.11 physical layer simulator in NS-3

Stylianos Papanastasiou

Signals and Systems  
stypap@chalmers.se

# Outline

Motivation

Planned activity

The implementation

Validation, tradeoffs

Future Work

# Physical layer abstractions in network level simulators

- ▶ Network simulators typically abstract the physical layer
- ▶ They use frame-level statistics
  - ▶ What happens to the frame?
  - ▶ (c.f. what happens to the signal?)
- ▶ Approach works well enough if the abstraction is reasonable
  - ▶ Ok in wired, not so well in wireless

# Reasonable abstractions

- ▶ Not always clear what to abstract and what not to
- ▶ It is not easy to extrapolate “general” characteristics
- ▶ Scenario-specific minute measurements may matter
- ▶ May want to examine network performance of PHY techniques
  - ▶ Receiver structure (Interference cancellation)
  - ▶ Synchronisation
  - ▶ Channel estimation

# Typical channel model development

- ▶ Channel Measurements → Channel Model → BER → PER
- ▶ Lost in translation? BER to PER conversion not trivial
- ▶ Would be useful to utilise Channel Model or Measurements directly
  - ▶ Expediency (no need to make PER calculations)
  - ▶ Accuracy (no compromises)

# Big picture - Layer division

- ▶ Network vs physical layer communities
- ▶ Packet vs signal time samples
- ▶ Coarse vs fine grained
- ▶ Network vs Link
- ▶ **Join the two perspectives in a single simulation tool**

# An idea (with KIT)

Integrate physical layer simulator for OFDM-based IEEE 802.11 communication in a network simulator

**CHALMERS**

**CHALMERS**

# Course of action

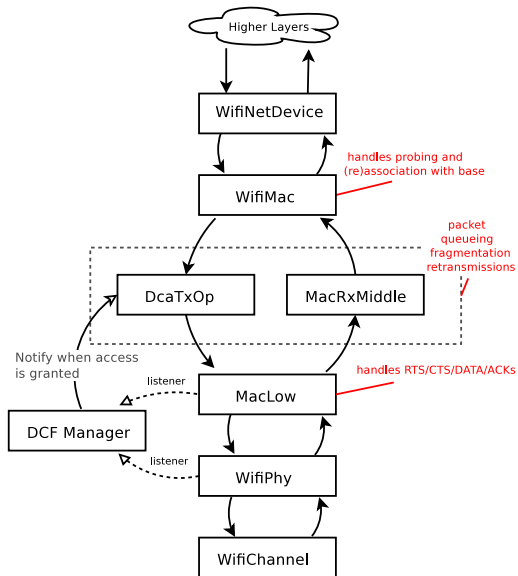

1. Use NS-3 – a popular, well maintained simulator
2. Develop and validate a physical layer simulator
  - ▶ Based on well-established signal processing library (IT++)
  - ▶ May have value as a standalone deliverable
3. Integrate the two – release to community for feedback

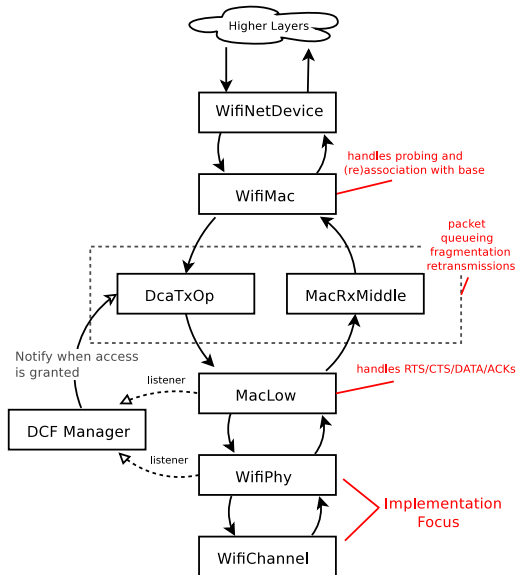

# Why use NS-3

- ▶ Very well maintained
- ▶ Open source (GPL)
- ▶ Speed and accuracy are a priority for maintainers
- ▶ Flexible architecture and very good documentation
- ▶ Actively used for research

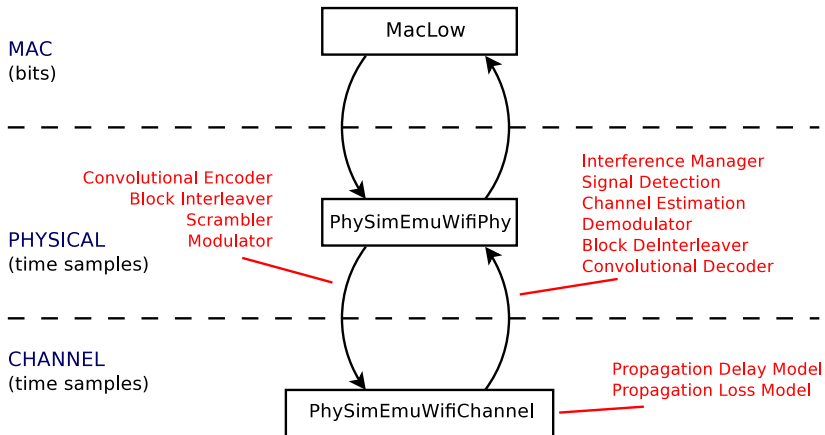

# NS-3 architecture

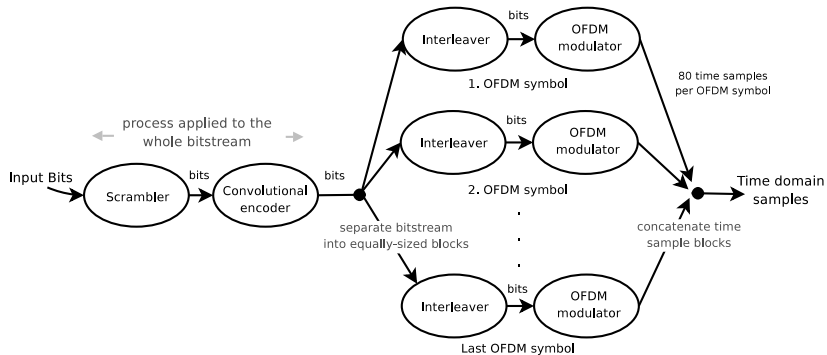

# NS-3 architecture (implementation)

# A new physical layer for NS-3

# Frame construction

# Channel modelling

- ▶ Channel models operate on time sample level
- ▶ Several have been implemented already
- ▶ Channel models can be “chained” in sequence

# Frame reception

- ▶ Frame reception handled realistically
- ▶ Signal detector tries to “lock-on” to frame
- ▶ Header is decoded and if successful the payload is examined too

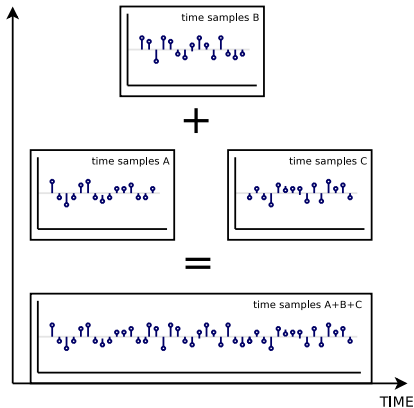

# Frame reception (2)

- ▶ At all times surrounding interference is accounted for
- ▶ For the superposition of signals some alignment is needed

# Frame reception (Old vs New)

# Integration into NS-3 state machine

- ▶ Reception process represented by 4 events
- ▶ Computations performed at each event
- ▶ Possibilities of computational “shortcuts”

# Example usage (standard model)

```
1  YansWifiChannelHelper wifiChannel;  
2  YansWifiPhyHelper wifiPhy = YansWifiPhyHelper::  
   Default();  
3  
4  wifiPhy.SetChannel(wifiChannel.Create());  
5  
6  WifiHelper wifi = WifiHelper::Default();  
7  NqosWifiMacHelper wifiMac = NqosWifiMacHelper::  
   Default();  
8  wifiMac.SetType("ns3::AdhocWifiMac");  
9  
10 NodeContainer nodes;  
11 nodes.Create(2);  
12 // Install WifiPhy and set up mobility  
13 wifi.Install(wifiPhy, wifiMac, nodes);
```

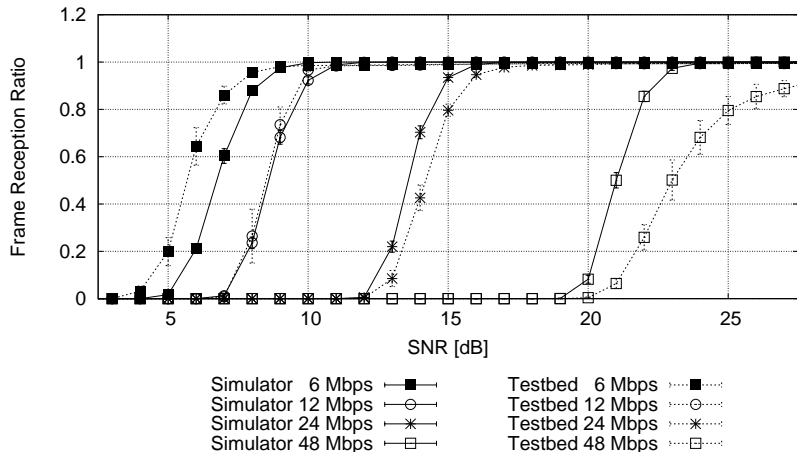

# Example usage (new model)

```
1  PhySimWifiChannelHelper wifiChannel ;
2  PhySimWifiPhyHelper wifiPhy = PhySimWifiPhyHelper ::
   Default () ;
3
4  wifiPhy . SetChannel ( wifiChannel . Create () ) ;
5
6  WifiHelper wifi = WifiHelper :: Default () ;
7  NqosWifiMacHelper wifiMac = NqosWifiMacHelper ::
   Default () ;
8  wifiMac . SetType ( "ns3 :: AdhocWifiMac" ) ;
9
10 NodeContainer nodes ;
11 nodes . Create ( 2 ) ;
12 // Install WifiPhy and set up mobility
13 wifi . Install ( wifiPhy , wifiMac , nodes ) ;
```

# Validation

- ▶ Validate produced samples against 802.11 Annex G.
- ▶ Common-sense cases (BER vs SINR)
- ▶ Verification against Octave/Matlab simulator and theoretical BER curves
- ▶ Against real transceivers done by KIT at CMU

# Validation (2)

Static pathloss, 500 bytes frame size, 10 Hz transmission freq.

# What is the tradeoff?

- ▶ Simulation becomes much more demanding
- ▶ Computational costs + memory overheads
  - ▶ Preliminary results indicate slowdown factor of 200 for simple pathloss
  - ▶ ...for complex channel slowdown factor increases to  $10^3$
  - ▶ Have to store whole frame representation in memory
- ▶ Work underway at Karlsruhe to increase speed for single user systems (OpenCL)

# Future work

- ▶ Integrate several new channel estimators (sometime in October/November)
- ▶ Implement more channel/frontend effects (phase noise, antenna diversity etc...)
- ▶ Implement environment/node geometry effects

# Where can I get all this?

- ▶ All items are open source (GPL) and available online
- ▶ Standalone physical layer simulator available
- ▶ ...as well as full NS-3 implementation
- ▶ Code is under review for inclusion in NS-3 in the near future

Thank you for your attention

Questions?

**Standalone physical layer simulator**

Does not include high-level protocols, mobility, etc...

<http://physlayersim.sourceforge.net>

**NS-3 simulator with new physical layer model**

Ported to the latest version of NS-3 (3.9)

<http://www.lefrog.at/NS-3.9-PhySimWiFi-1.0.tar.bz2>
